We know from basic Physics...

e

The Sub-atomic Particles			
Relative size	Name	Mass (Kg)	Charge (C)
	Proton	1.67×10^{-27}	$+1.602 \times 10^{-19}$
	Neutron	1.67×10^{-27}	0
	Electron	9.11×10^{-31}	-1.602×10^{-19}

Q. Do you see any other convention at play here?

The claim that electron is "negatively" charged is also a convention!

“Charge”

The Workhorse...

*Formally
speaking*

Charge is an electrical property of the atomic particles of which matter consists, measured in coulombs (C).

“Charge”

The Workhorse...

*Formally
speaking*

Charge is an electrical property of the atomic particles of which matter consists, measured in coulombs (C).

- In fact, we generally deal with only two workhorses (**elementary charges**) – **electron** and **proton**.

“Charge”

The Workhorse...

*Formally
speaking*

Charge is an electrical property of the atomic particles of which matter consists, measured in coulombs (C).

- In fact, we generally deal with only two workhorses (**elementary charges**) – **electron** and **proton**.
- Remaining charges are *mostly* based on these and are therefore multiples of e .

10^{-12}	
10^{-14}	Synaptic current (brain cell)

“Current”

Some interesting bits...

“Current”

Some interesting bits...

- The “point” across which current is supposed to flow is actually an arbitrary cross section!

“Current”

Some interesting bits...

- The “point” across which current is supposed to flow is actually an arbitrary cross section!

■ **FIGURE 2.1** The definition of current illustrated using current flowing through a wire; 1 ampere corresponds to 1 coulomb of charge passing through the arbitrarily chosen cross section in 1 second.

“Current”

Some interesting bits...

- Current Can be Fixed or Time-Varying!
- That is, the net rate of flow of charge may itself varying.

"Current"

Some interesting bits...

- Current Can be Fixed or Time-Varying!
- That is, the net rate of flow of charge may itself vary.

■ **FIGURE 2.4** Several types of current: (a) Direct current (dc). (b) Sinusoidal current (ac). (c) Exponential current. (d) Damped sinusoidal current.

The two most common types of current are AC and DC

Electrical appliances
typically use AC.

Electrical appliances
typically use AC.

Electronic
and battery-
operated
devices are
typically DC.

Electrical appliances typically use AC.

Electronic and battery-operated devices are typically DC.

Power transmission systems and your home socket are also AC.

Why? Answers in Electric Circuits-II!

HW: Read up on the **AC-DC War** and how the two may actually complement each other now!

THE GREAT WAR OF THE CURRENTS

NIKOLA TESLA

AC vs DC

POWER TRANSMISSION

THOMAS EDISON

When projecting Europe's future electricity infrastructure systems, discussions revolve around two possible transmission technologies: Alternate Current (AC) and Direct Current (DC).

Today, the two technologies are seen as complementary: AC power transmission is suitable for relatively short connections while DC is the most appropriate technol-

ogy for carrying high power over long distances practically without any losses. At present, Europe's networks are based on meshed AC electricity grids. In the

future, these will be complemented by a high power DC overlay network. While DC connections today are typically used to transmit or exchange power point-to-point, meshed or multi-terminal DC grids will become available as HVDC switchgear technology gains market access.

This complementarity was not always the case. In the late 19th century, Nikola Tesla laid the foundations of today's alternating current electricity supply systems. Around the same time, Thomas Edison set up an

extended DC system for the illumination of New York City.

Today Tesla's AC systems operate Europe's electricity systems but we can be confident that Edison's dream to create a DC overlay net will become a reality in Europe in the near future. With that, the fierce "war of the currents" fought between two of the world's most ingenious minds will have been settled in a peaceful co-existence.

We've seen two conventions so far, let's look at a third one...

Conventional Current

What's Flowing?

- Recall that we represented current by a magnitude and direction of flow.

What's Flowing?

- Recall that we represented current by a magnitude and direction of flow.
- **As a convention, the current we show in circuits is a flow of positive charges!**

What's Flowing?

- Recall that we represented current by a magnitude and direction of flow.
- **As a convention, the current we show in circuits is a flow of positive charges!**
- This is so even when we know that in fact negative charges may be flowing (as is the case for free electrons).

What's Flowing?

- Recall that we represented current by a magnitude and direction of flow.
- **As a convention, the current we show in circuits is a flow of positive charges!**
- This is so even when we know that in fact negative charges may be flowing (as is the case for free electrons).
- We can get away with it, as the flow of positive charge in one direction is equivalent to flow of negative charge in the opposite direction!

Conventional Current

Electron Current

- So from now on, this figure means “an equivalent of 5 C of positive charge is flowing to the right per second”.

- So from now on, this figure means “an equivalent of 5 C of positive charge is flowing to the right per second”.

Q. Suppose that 10 C of negative charge is flowing in this wire to the left each second. How would you show the “current” diagrammatically?

- So from now on, this figure means “an equivalent of 5 C of positive charge is flowing to the right per second”.

Q. Suppose that 10 C of negative charge is flowing in this wire to the left each second. How would you show the “current” diagrammatically?

Q. Suppose that 4 C of positive ions are flowing to the right and 8 C of negative ions are flowing to the left per second in this electrolyte. How would you show current flow in the electrolyte for this case?

Q. Suppose that 4 C of positive ions are flowing to the right and 8 C of negative ions are flowing to the left per second in this electrolyte. How would you show current flow in the electrolyte for this case?

Q. If we know the current flow over a period of time, can we tell how much charge got transferred in this time?

Q. If we know the current flow over a period of time, can we tell how much charge got transferred in this time?

$$i \triangleq \frac{dq}{dt}$$

Q. If we know the current flow over a period of time, can we tell how much charge got transferred in this time?

$$i \triangleq \frac{dq}{dt}$$

$$Q \triangleq \int_{t_0}^t i \, dt$$

Q. If we know the current flow over a period of time, can we tell how much charge got transferred in this time?

$$i \triangleq \frac{dq}{dt}$$

$$Q \triangleq \int_{t_0}^t i \, dt$$

“Voltage”

“Voltage”

Energy absorbed or spent (by unit charge) during flow

“Voltage”

Energy absorbed or spent (by unit charge) during flow

*Formally
speaking...*

Voltage (or **potential difference**) is the energy required to move a unit charge through an element, measured in volts (V).

“Voltage”

Energy absorbed or spent (by unit charge) during flow

Formally speaking...

Voltage (or **potential difference**) is the energy required to move a unit charge through an element, measured in volts (V).

Mathematically...

$$v_{ab} \triangleq \frac{dw}{dq}$$

“Voltage”

Energy absorbed or spent (by unit charge) during flow

Formally speaking...

Voltage (or **potential difference**) is the energy required to move a unit charge through an element, measured in volts (V).

Mathematically...

$$v_{ab} \triangleq \frac{dw}{dq}$$

$q = \text{charge (C)}$
 $w = \text{energy (J)}$
 $v_{ab} = \text{voltage (J/C)}$

“Voltage”

Energy absorbed or spent (by unit charge) during flow

Formally speaking...

Voltage (or **potential difference**) is the energy required to move a unit charge through an element, measured in volts (V).

Mathematically...

$$v_{ab} \triangleq \frac{dw}{dq}$$

$q = \text{charge (C)}$
 $w = \text{energy (J)}$
 $v_{ab} = \text{voltage (J/C)}$

$$1 \text{ volt} = 1 \text{ joule/coulomb} = 1 \text{ newton-meter/coulomb}$$

"Voltage"

Diagrammatically...

"Voltage"

Diagrammatically...

Keep in mind that

- Voltage is the difference of potential between two points.
- Therefore, it cannot be defined with one point only.

"Voltage"

Diagrammatically...

Keep in mind that

- Voltage is the difference of potential between two points.
- Therefore, it cannot be defined with one point only.

Potential and Potential Difference

“Voltage”

Diagrammatically...

Keep in mind that

- Voltage is the difference of potential between two points.
- Therefore, it cannot be defined with one point only.

Potential and Potential Difference

- We could define potential at a w.r.t. a hypothetical “ground” point where the potential is zero
 - $V_a = v_{ag}$
- Same goes for potential at b
 - $V_b = v_{bg}$

“Voltage”

Diagrammatically...

Keep in mind that

- Voltage is the difference of potential between two points.
- Therefore, it cannot be defined with one point only.

Potential and Potential Difference

- We could define potential at a w.r.t. a hypothetical “ground” point where the potential is zero
 - $V_a = v_{ag}$
- Same goes for potential at b
 - $V_b = v_{bg}$

- Then it is easy to see that $v_{ab} = V_a - V_b$
 - i.e., the voltage at a w.r.t. b is the potential at a minus the potential at b
- And $v_{ba} = V_b - V_a$

“Voltage”

Diagrammatically...

Keep in mind that

- Voltage is the difference of potential between two points.
- Therefore, it cannot be defined with one point only.

Potential and Potential Difference

A fourth convention...

A truly positive terminal is at a higher potential

A truly positive terminal is at a higher potential

“Truly Positive”?

- We could arbitrarily label any terminal positive.
- However, if it is not actually at higher potential, we will get a negative voltage value.

A fourth convention...

A truly positive terminal is at a higher potential

Why?

"Truly Positive"?

- We could arbitrarily label any terminal positive.
- However, if it is not actually at higher potential, we will get a negative voltage value.

A fourth convention...

A truly positive terminal is at a higher potential

“Truly Positive”?

- We could arbitrarily label any terminal positive.
- However, if it is not actually at higher potential, we will get a negative voltage value.

Why?

- Recall that by the direction of current convention, we are looking at flow of positive charge.

A fourth convention...

A truly positive terminal is at a higher potential

“Truly Positive”?

- We could arbitrarily label any terminal positive.
- However, if it is not actually at higher potential, we will get a negative voltage value.

Why?

- Recall that by the direction of current convention, we are looking at flow of positive charge.
- A positive charge should lose potential as it goes away from positive terminal.
 - i.e., for a positive charge $V_a > V_b$, leading to $v_{ab} = V_a - V_b > 0$

A truly positive terminal is at a higher potential

“Truly Positive”?

- We could arbitrarily label any terminal positive.
- However, if it is not actually at higher potential, we will get a negative voltage value.

Why?

- Recall that by the direction of current convention, we are looking at flow of positive charge.
- A positive charge should lose potential as it goes away from positive terminal.
 - i.e., for a positive charge $V_a > V_b$, leading to $v_{ab} = V_a - V_b > 0$
- If we mistakenly assign + to a terminal at low potential, then this will be made clear to us by the voltage turning out negative
 - As then $v_{ba} = V_b - V_a < 0$

Q. Can you describe these in words?

(a)

(b)

(c)

(d)

Q. Can you describe these in words?

(a)

(b)

(c)

(d)

(a) Potential at B is 5 V higher than at A

(b) Potential at B is 5 V higher than at A

Q. Can you describe these in words?

(a)

(b)

(c)

(d)

(a) Potential at B is 5 V higher than at A

(b) Potential at B is 5 V higher than at A

(c) Potential at A is 5 V higher than at B

(d) Potential at A is 5 V higher than at B

Next time, we look at more terms and conventions...

Questions?? Thoughts??
